NOAA: 'Nuisance flooding' an increasing problem as coastal sea levels rise

Study looks at more than 60 years of coastal water level and local elevation data changes

July 28, 2014

Eight of the top 10 U.S. cities that have seen an increase in so-called "nuisance flooding"--which causes such public inconveniences as frequent road closures, overwhelmed storm drains and compromised infrastructure--are on the East Coast, according to a new NOAA technical report.

This nuisance flooding, caused by rising sea levels, has increased on all three U.S. coasts, between 300 and 925 percent since the 1960s.

The report, [Sea Level Rise and Nuisance Flood Frequency Changes around the United States](#),

also finds Annapolis and Baltimore, Maryland, lead the list with an increase in number of flood days of more than 920 percent since 1960. Port Isabel, Texas, along the Gulf coast, showed an increase of 547 percent, and nuisance flood days in San Francisco, California increased 364 percent.

"Achieving resilience requires understanding environmental threats and vulnerabilities to combat issues like sea level rise," says Holly Bamford, Ph.D., NOAA assistant administrator of the National Ocean Service. "The nuisance flood study provides the kind of actionable environmental intelligence that can guide coastal resilience efforts."

"As relative sea level increases, it no longer takes a strong storm or a hurricane to cause flooding," said William Sweet, Ph.D., oceanographer at NOAA's [Center for Operational Oceanographic Products and Services \(CO-OPS\)](#) and the report's lead author. "Flooding now occurs with high tides in many locations due to climate-related sea level rise, land subsidence and the loss of natural barriers. The effects of rising sea levels along most of the continental U.S. coastline are only going to become more noticeable and much more severe in the coming decades, probably more so than any other climate-change related factor."

The study was conducted by scientists at CO-OPS, who looked at data from 45 [NOAA water level gauges](#) with long data records around the country and compared that to reports of number of days of nuisance floods.

Assertion #2

Very few development decisions being made today in vulnerable coastal communities are considering the consequences in a worst-case scenario at 2100.

Millions projected to be at risk from sea-level rise in the continental United States

Mathew E. Hauer^{1*}, Jason M. Evans² and Deepak R. Mishra³

Sea-level rise (SLR) is one of the most apparent climate change stressors facing human society¹. Although it is known that many people at present inhabit areas vulnerable to SLR^{2,3}, few studies have accounted for ongoing population growth when assessing the potential magnitude of future impacts⁴. Here we address this issue by coupling a small-area population projection with a SLR vulnerability assessment across all United States coastal counties. We find that a 2100 SLR of 0.9 m places a land area projected to house 4.2 million people at risk of inundation, whereas 1.8 m affects 13.1 million people—approximately three times larger than indicated by current populations. These results suggest that the absence of protective measures could lead to US population movements of a magnitude similar to the twentieth century Great Migration of southern African-Americans⁵. Furthermore, our population projection approach can be readily adapted to assess other hazards or to model future per capita economic impacts.

Sea-level rise is widely recognized as one of the most likely and socially disruptive consequences of future climate change². Scenarios of future SLR at the year 2100 range from a low of 0.3 m to a high scenario of 2.0 m associated with collapse of polar ice sheets³. Understanding the specific locations at risk of SLR impacts is a high priority in climate change research⁶ and adaptation planning^{7,8}.

Although there is growing worry and debate that climate change could cause widespread human migration over the next century^{2,9,10}, relatively few studies have attempted to merge climate change scenarios with population growth trends and projections in high-risk areas (however, see ref. 11). Notably, several previous studies

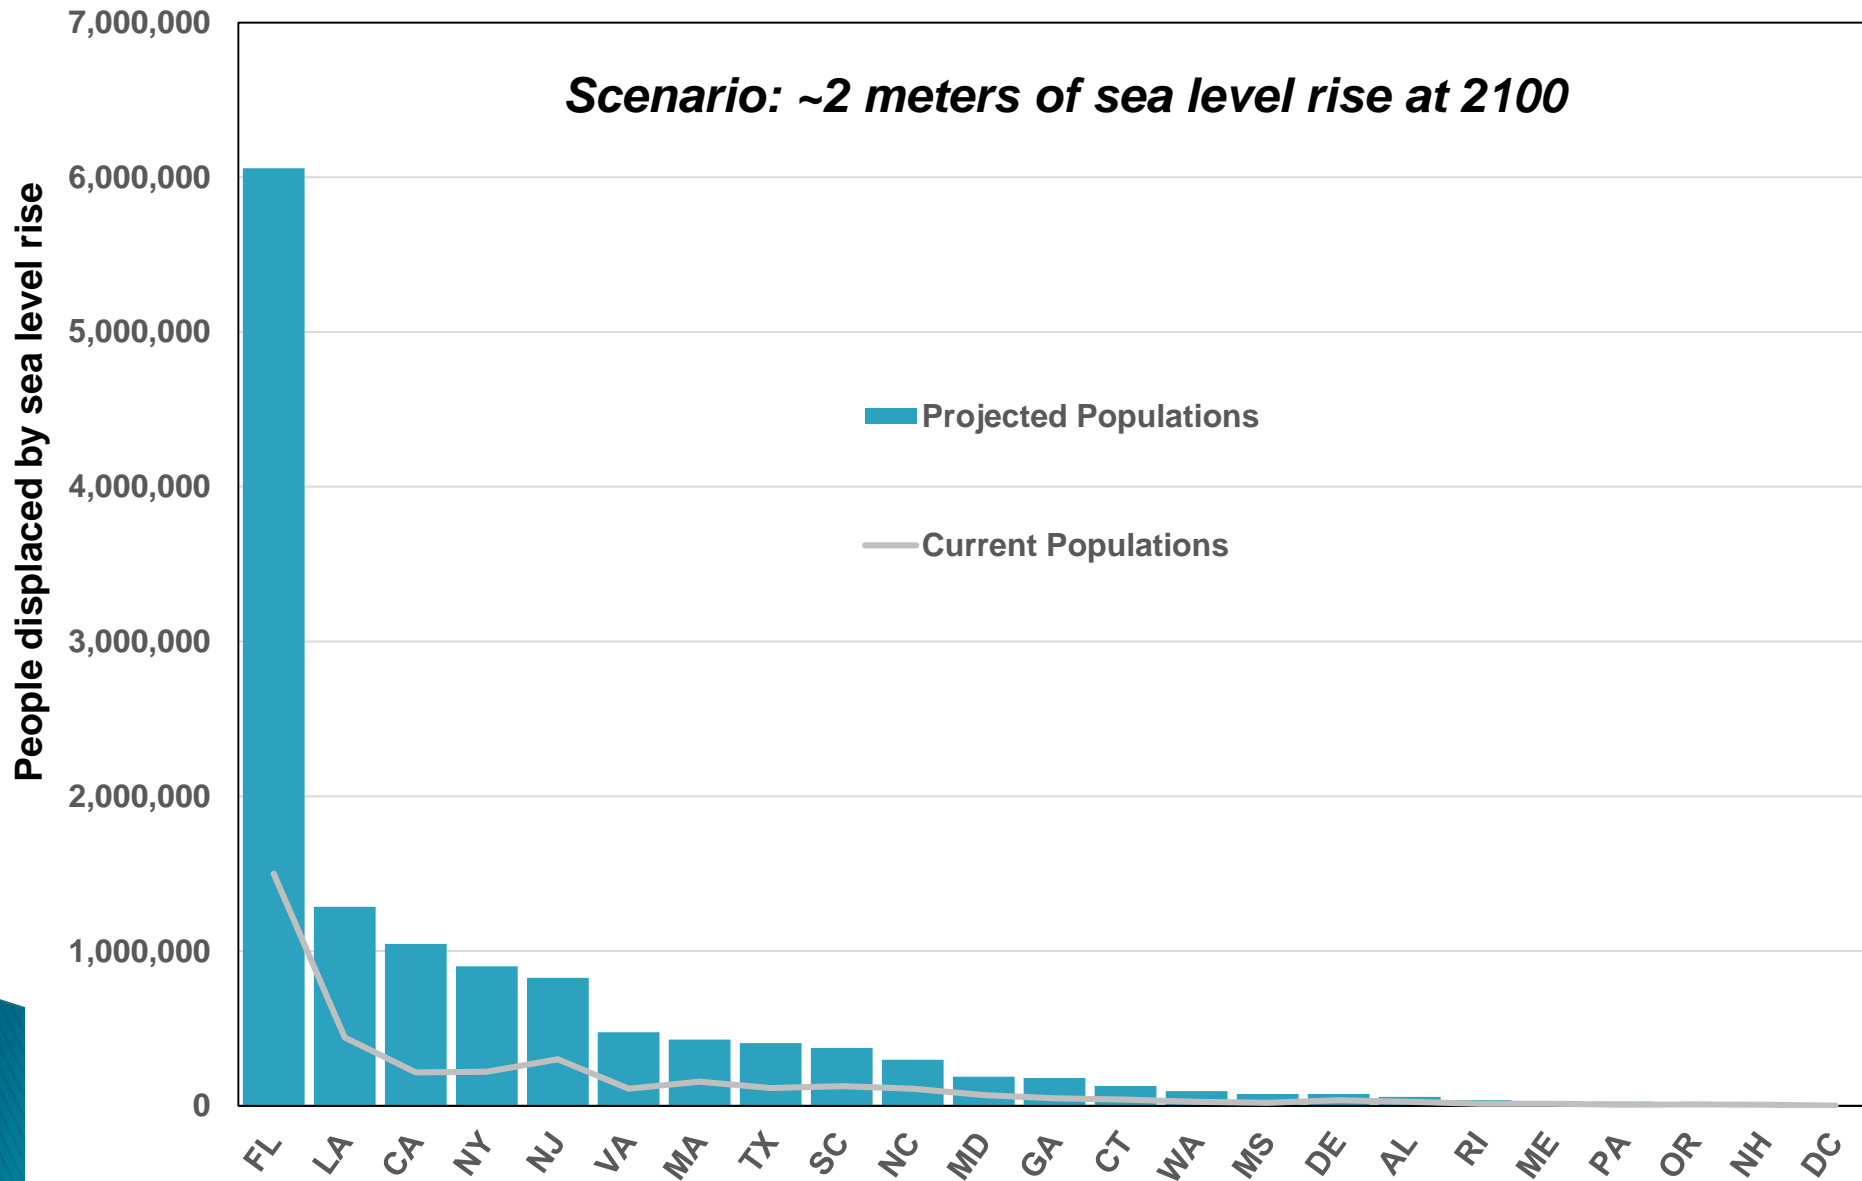

data (that is, elevation and associated flood risk) with small-area population projections developed with a modified version of the Hammer method^{17,18} in a dynamic flood hazard model. By spatially and temporally aligning small-area population projections from coastal states in the continental United States (US) to 2100, we are able to assess who could be at risk from future SLR.

This approach addresses two fundamental questions concerning the vulnerability of future coastal populations in the United States: How many people are potentially at risk of impact from SLR? and What areas in the US are likely to experience the greatest population exposure to SLR? Accordingly, our results can be used to inform local adaptation infrastructure and growth management strategies, alerting officials to the areas where interventions and policies are most needed.

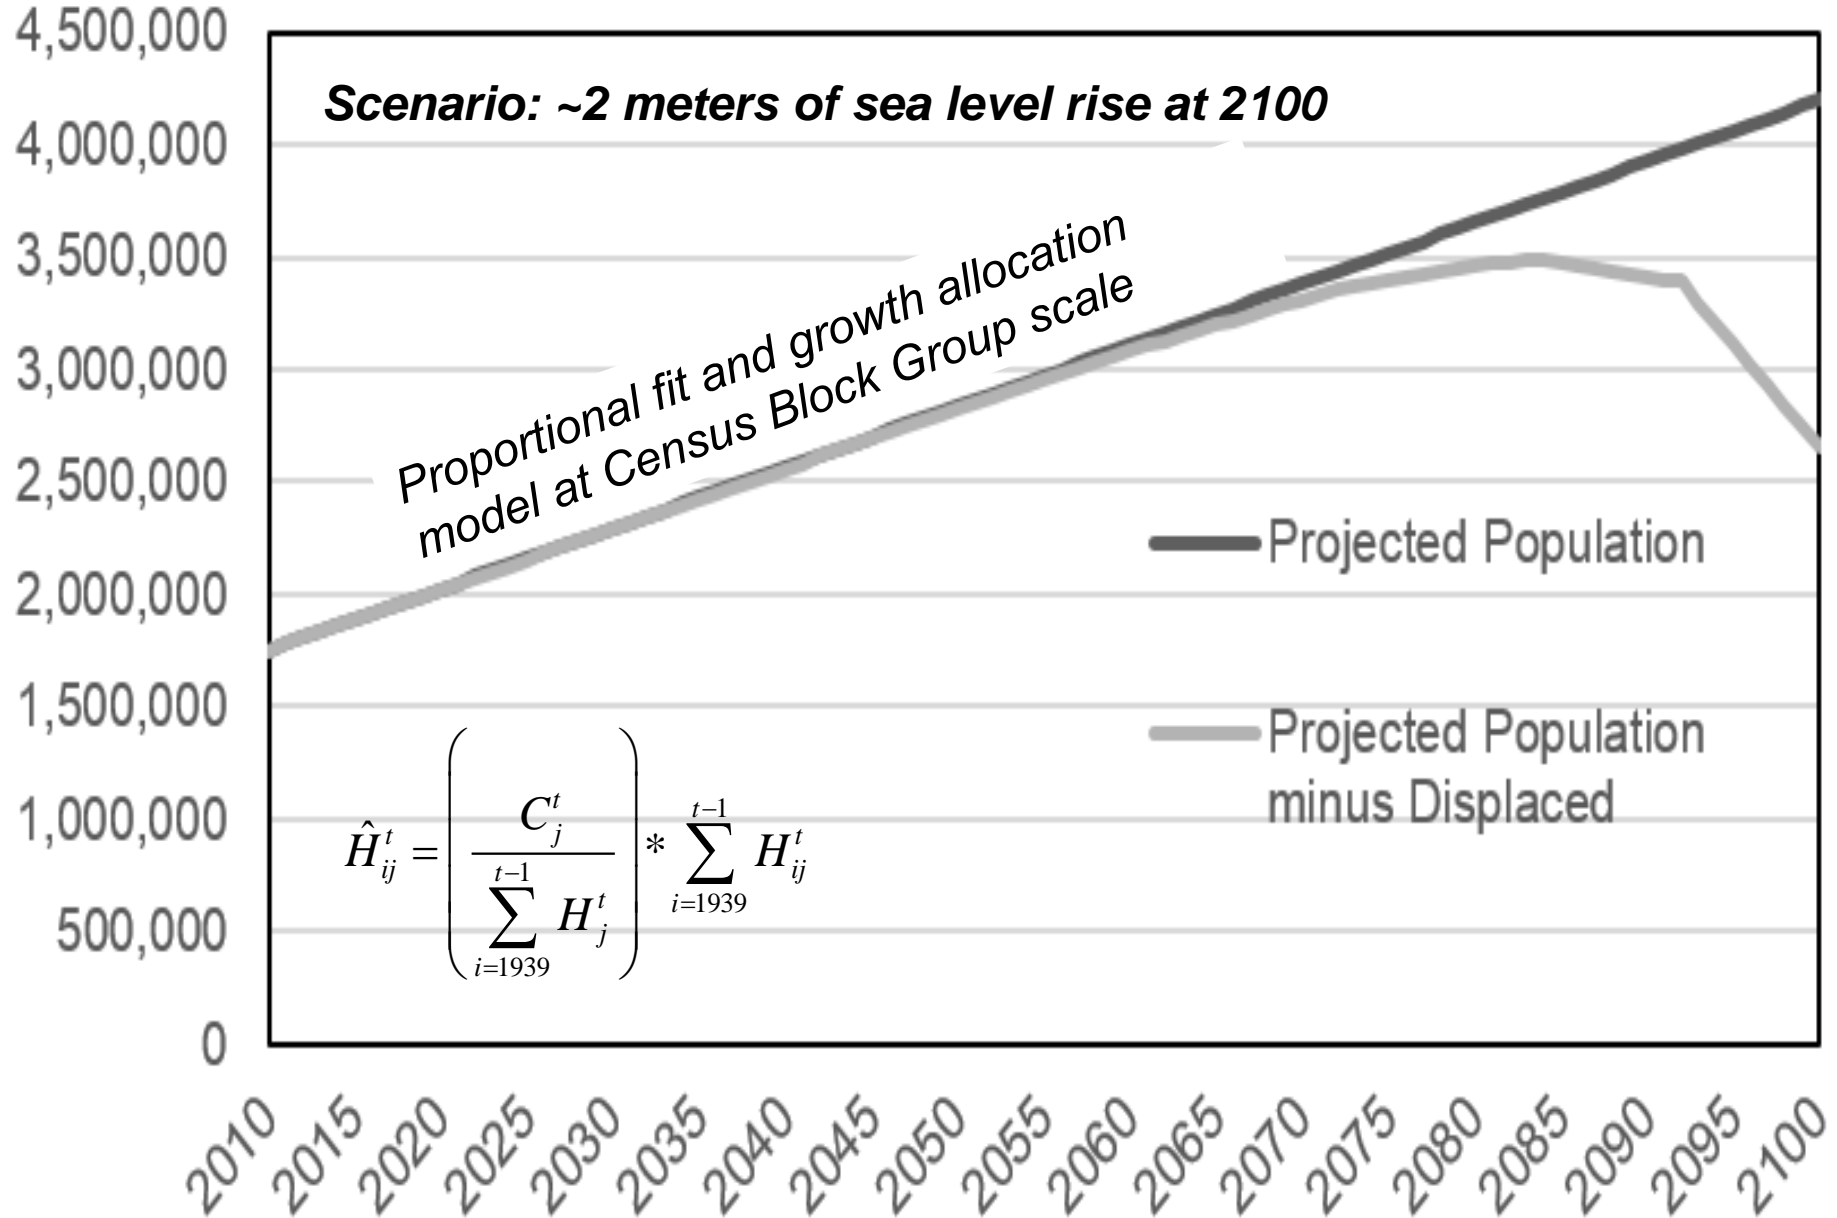

We assess the populations at risk of SLR by using the National Oceanic and Atmospheric Administration's (NOAA) 0 m through 1.8 m (6 feet) SLR data sets for twenty-two coastal states and the District of Columbia¹⁹. These data sets simulate expected changes in the mean higher high water (MHHW) mark on areas that are hydrologically connected to coastal areas, without taking into account additional land loss caused by other natural factors such as erosion. Notably, the state of Louisiana was not included in the data set at the time of analysis owing to local hydrologic complexities associated with coastal levees and accelerated land subsidence; however, we have recreated NOAA's hydrologic connectedness approach for Louisiana using USGS's National Elevation Dataset (NED) (Methods).

We used a linear/exponential extrapolation approach for

Assertion #3

Very few development decisions being made today in vulnerable coastal communities are considering the consequences in a worst-case scenario at 2100.

This is understandable – even appropriate – given uncertainty about the future over such a long time-horizon.

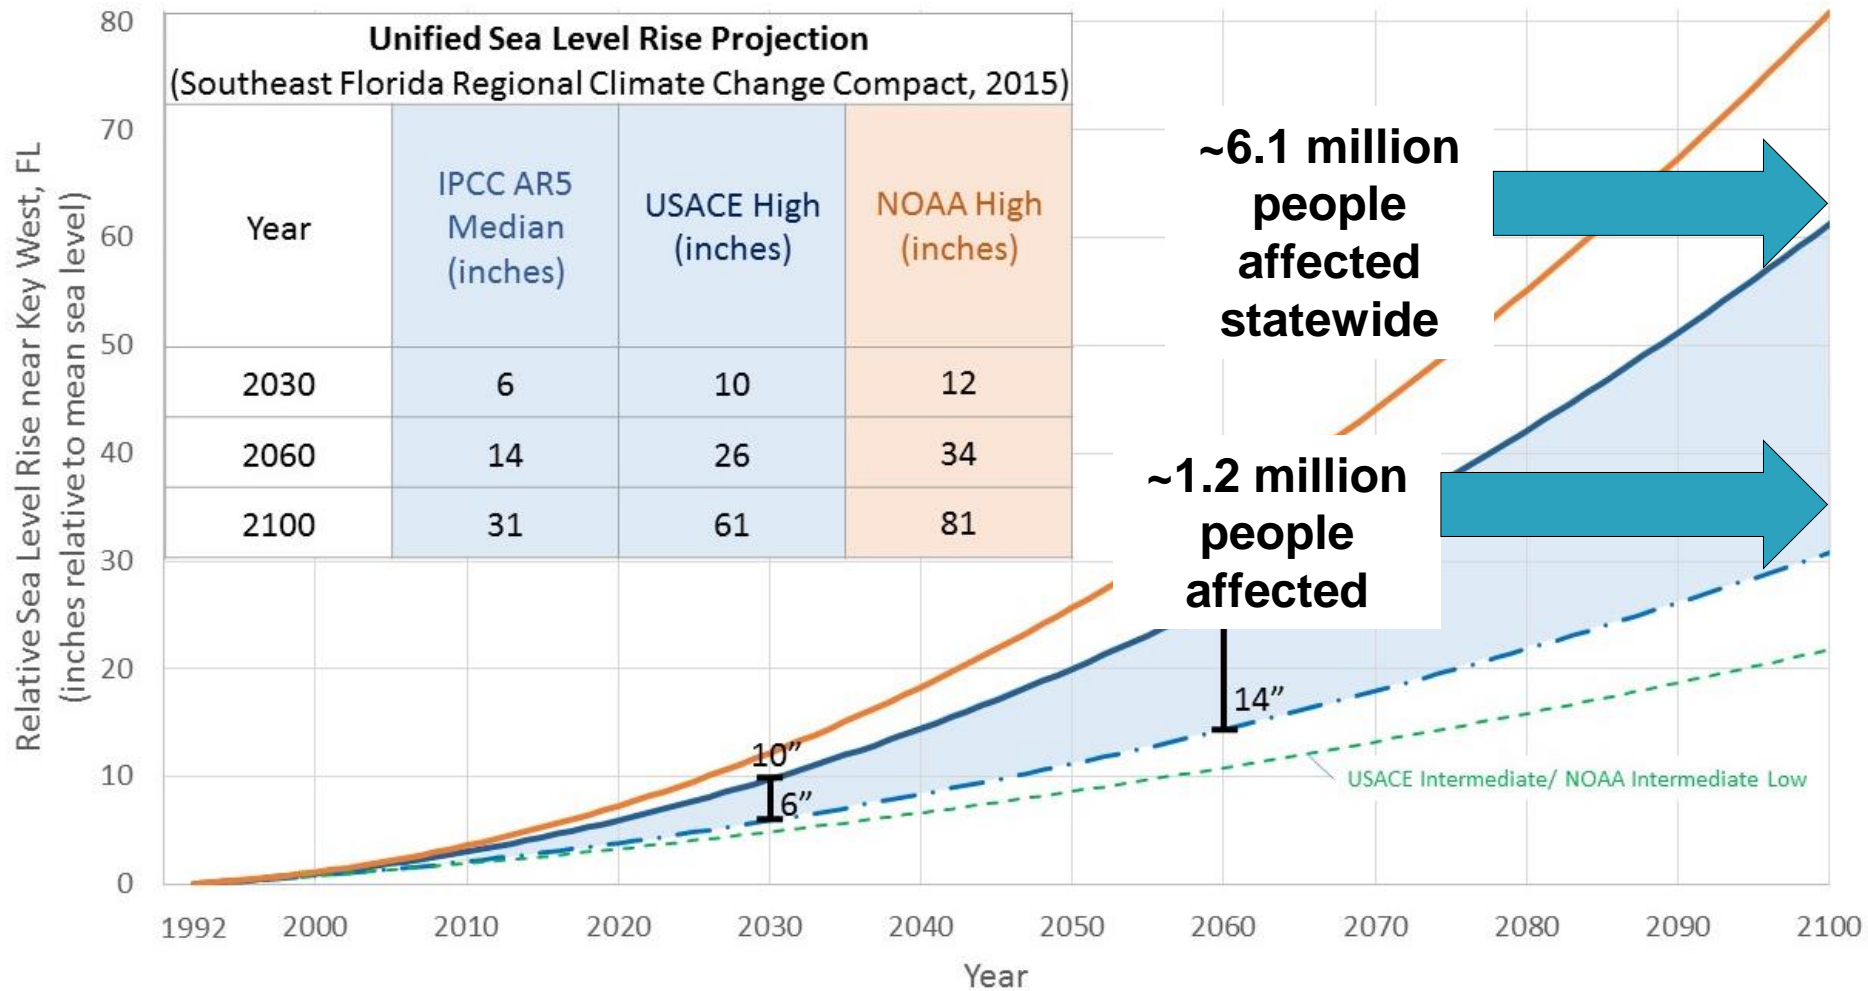

"Scientists have very high confidence that global mean sea level will rise at least 8 inches and no more than 6.6 feet by 2100."

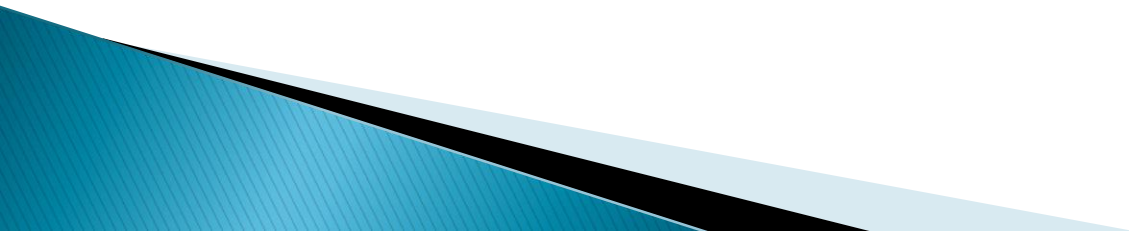

NOAA REPORT, DEC. 2012

BIG difference between low and high scenario

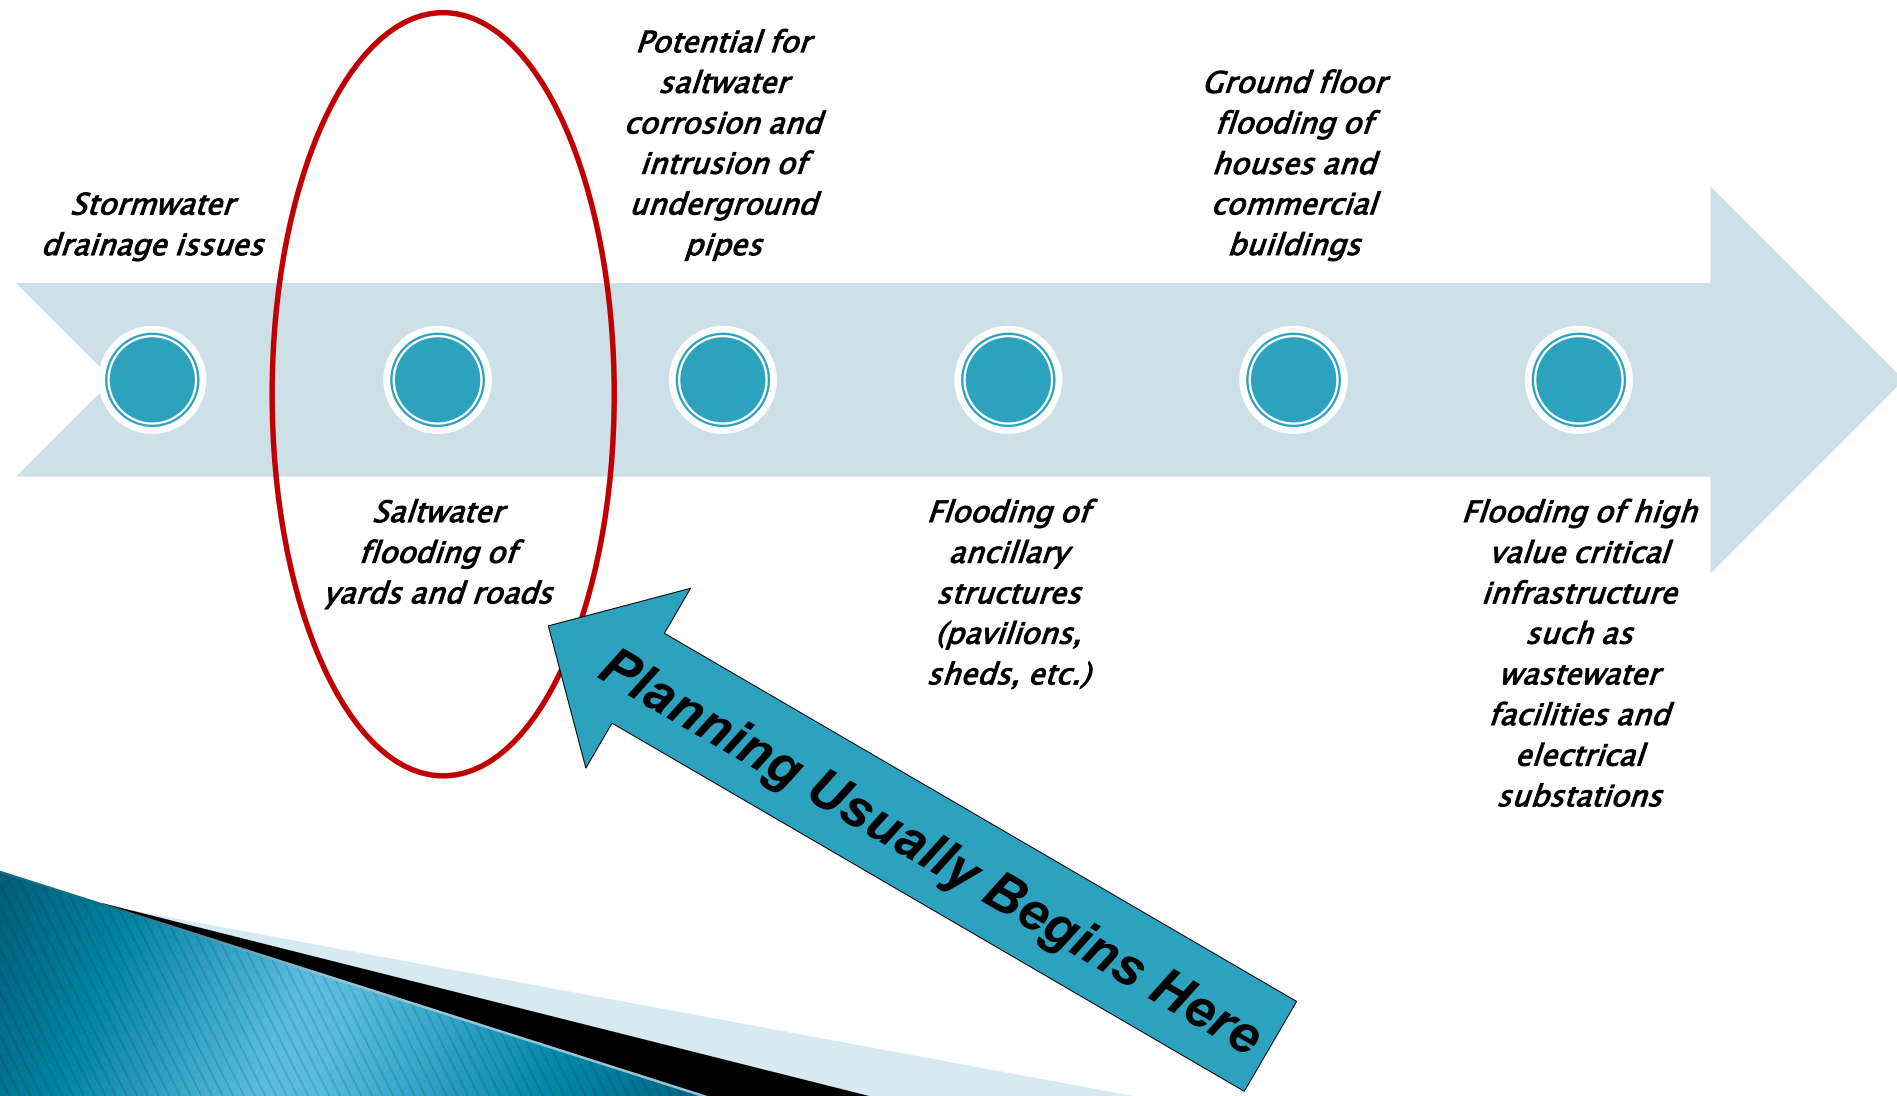

Assertion #4

People start to really take notice when roads start flooding on a sunny day.

Modeling: More Accurate by the Day Policy

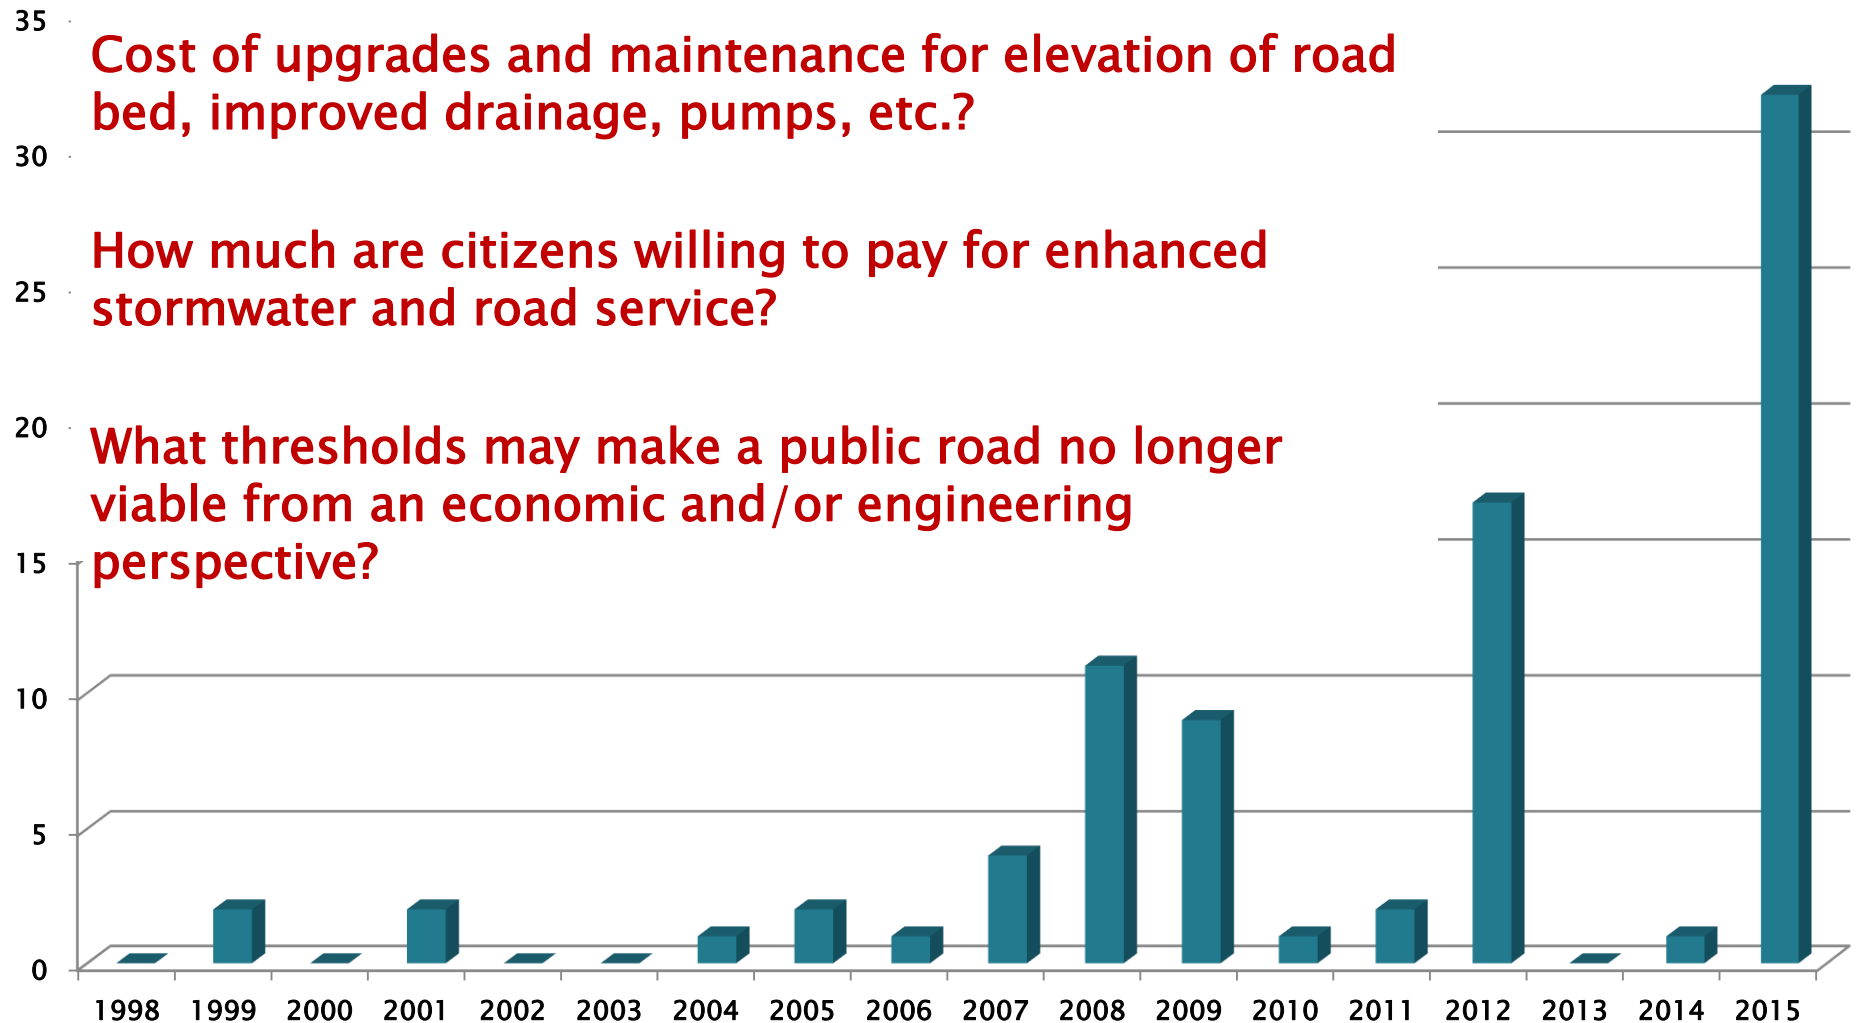

Framing: Much More Difficult

What is an appropriate level of service for maintaining stormwater and roads under sea level rise?

Cost of upgrades and maintenance for elevation of road bed, improved drainage, pumps, etc.?

How much are citizens willing to pay for enhanced stormwater and road service?

What thresholds may make a public road no longer viable from an economic and/or engineering perspective?
